Supporting Methods: The basics SVM is one of the most popular models to use for classification. It can be used for regression or ranking as well, but its the most common use case is classification. SVM is often used for image or text classification, face or speech recognition, document categorization.

An introduction to support vector machines

The name Support Vector Classifier comes from the fact that the observations on the edge and within the Soft Margin are called Support Vectors. Now, if each observation has not only the Mass (g) measurement but also the Height (cm) measurement, then the data would be two-dimensional; in this case the Support Vector Classifier is a line.

Introduction to Support Vector Machine - Andrea Perlatò

A support vector machine (SVM) is a non-probabilistic binarylinear classifier. The non- probabilistic aspect is its key strength. This aspect is in contrast with probabilistic classifiers such as the Naïve Bayes. That is, an SVM separates data across a decision boundary (plane) determined by only a small subset of the data (feature vectors).

we maximize the margin of the classifier. Deleting the support vectors will change the position of the hyperplane. These are the points that help us build our SVM.

Introduction to SVM Support vector machines (SVMs) are powerful yet flexible supervised machine learning algorithms which are used both for classification and regression. But generally, they are used in classification problems. In 1960s, SVMs were first introduced but later they got refined in 1990.
