Many embedded systems can be characterized as real time. A real-time system is one in which the correctness of the computations not only depends on their logical correctness, but also on the time at which the result is produced. In other words, a late answer is a wrong answer. As an example of a real-time system, consider a computer-controlled machine on the production line at a bottling plant.

Embedded systems are also known as real time systems since they respond to an input or event and produce the result within a guaranteed time period. This time period can be few microseconds to days or months. Real time systems are further classified as hard real time systems and soft real time systems, based

on the strictness to the time period.
